# 1. Dynamic Programming

Some of the harder problems in dynamic programming with insightful solutions.

## 1.1 Counting Towers

### 1.1.1 Statement

Your task is to build a tower whose width is 2 and height is  $n$ . You have an unlimited supply of blocks whose width and height are integers.

Given  $n$ , how many different towers can you build? Mirrored and rotated towers are counted separately if they look different.

**Input:** The first input line contains an integer  $t$ : the number of tests. After this, there are  $t$  lines, and each line contains an integer  $n$ : the height of the tower.

**Output:** For each test, print the number of towers modulo  $10^9 + 7$ .

**Constraints:**  $1 \leq t \leq 100$ ,  $1 \leq n \leq 10^6$

**Example:**

Input:

3

2

6

1337

Output:

8

2864

640403945

### 1.1.2 Solution

This is a particularly neat problem, in that it is tempting to write a recurrence that multiplies successive tilings at various points. However, such combinatorial logic is rarely (if ever) useful for DP.

Instead, consider ‘building’ the tower from a position  $i$ , somewhere in the middle of the tower.

$\vdots$	$\vdots$
	$i$
$\vdots$	$\vdots$

Okay, so we’re somewhere in what is clearly going to be a DP sequence. When in such a position, it’s always useful to analyze the *options* we have, as though we’re playing a game. As in a game,

our options are based off the state of the board the opponent left us with. Let us therefore consider the  $i - 1$  th tower row to see our options.

Clearly, it can be in any one of the following two states:

⋮	⋮
	$i$
⋮	⋮

(bool is true)

Or,

⋮	⋮
	$i$
⋮	⋮

(bool is false)

Alright. Convince yourself that  $i - 1$  has no other possibilities: either joint or broken. Each of these cases of  $i - 1$  means very different options for when we're at  $i$ , so let's define a `bool` that is true when the tiles are joined.

Now, in the `bool` is false case, the options are:

1. Extend both.

⋮	⋮
⋮	⋮

2. Close one, extend the other.

⋮	⋮
⋮	⋮

⋮	⋮
⋮	⋮

3. Close both. This presents the same two options for our current cell:

- (a) Make two tiles.

⋮	⋮
⋮	⋮

- (b) Make one fat tile.

⋮	⋮
⋮	⋮

On the other hand, if `bool` is true,

1. Extend the fat tile.

⋮	⋮
⋮	⋮

2. Close the fat tile. This presents the same two options as (3) for our current cell:

- (a) Make two tiles.

⋮	⋮
⋮	⋮

- (b) Make one fat tile.

⋮	⋮
⋮	⋮

Hopefully, you see what we're getting at here:  $i + 1$  has the same set of options to select from as  $i$  did, and we can define a `bool` for every successive floor in the tower.

Let us therefore define two recursions, one for the `bool` 0 case and one for the 1 case.

$$f(i, 0) = f(i + 1, 0) + 2 \times f(i + 1, 0) + f(i + 1, 0) + f(i + 1, 1)$$

$$f(i, 1) = f(i + 1, 1) + f(i + 1, 0) + f(i + 1, 1)$$

Or, combining like terms,

$$f(i, 0) = 4 \times f(i + 1, 0) + f(i + 1, 1)$$

$$f(i, 1) = 2 \times f(i + 1, 1) + f(i + 1, 0)$$

Let's DP this in C++.

```

1  #include <bits/stdc++.h>
2
3  long int dp[1000001][2];
4  int main(void)
5  {
6      dp[1][1] = dp[1][0] = 1;
7      for (int i = 2; i < 1000001; ++i) {
8          dp[i][0] = ((dp[i-1][0] * 4) + dp[i-1][1]) % 1000000007;

```

```

9      dp[i][1] = ((dp[i-1][1] * 2) + dp[i-1][0]) % 1000000007;
10    }
11
12    std::cout << (dp[2][0] + dp[2][1]) % 1000000007 << "\n";
13    std::cout << (dp[6][0] + dp[6][1]) % 1000000007 << "\n";
14    std::cout << (dp[1337][0] + dp[1337][1]) % 1000000007 << "\n";
15    return 0;
16  }

```

8

2864

640403945

For CSES, you'll have to take an input on STDIN for testcases and output  $(dp[n][0] + dp[n][1]) \% 1000000007$  according to  $n$ .
